- Qt is a cross-platform application and UI framework in C++.
- Using Qt, one can write GUI applications once and deploy them across desktop, mobile and embedded operating systems without rewriting the source code.
- Qt is supported on a variety of 32-bit and 64-bit platforms (Desktop, embedded, mobile):
  - Windows (MinGW, MSVS)
  - Linux (gcc)
  - Apple Mac OS
  - Mobile / Embedded (Windows CE, Windows Mobile, Symbian, Embedded Linux)

### Ot toolkit II

- Language bindings are available in C#, Java, Python(PyQt), Ada, Pascal, Perl, PHP(PHP-Qt), Ruby(RubyQt).
- Qt is available under GPL v3, LGPL v2 and commercial license.
- Real applications developed using Qt: Google Earth, KDE (desktop environment for Unix-like OS), Adobe Photoshop Album.
- Qt documentation: http://doc.qt.io/qt-5/.

Please see the tutorial on how to install Qt Library at <a href="http://www.cs.ubbcluj.ro/~iuliana/oop/">http://www.cs.ubbcluj.ro/~iuliana/oop/</a> - Tutorials

- Qt can be used with Microsoft Visual Studio as well as with Eclipse (provided there is a C++ compiler installed).
- There is also an IDE which is part of the SDK for the Qt GUI Application development framework - QtCreator. This also needs a C++ compiler.

Common pattern to build a GU  Create a new Qt application, as described in the tutorial mentioned on the previous slide.

 Edit the file main.cpp: add a new QLabel and display it, as follows:

```
#include <QtWidgets/QApplication>
#include <QtWidgets/QLabel>

int main(int argc, char *argv[])
{
    QApplication a(argc, argv);
    QLabel label("Hello world!");
    label.show();
    return a.exec();
}
```

nianagemeni

Common pattern to build a GUI The QApplication class manages the GUI application's control flow and main settings.

- QApplication contains the main event loop, where all events from the window system and other sources are processed and dispatched.
- For any GUI application using Qt, there is exactly one QApplication object (no matter how many windows the application has at any given time). This object is accessible using the function instance().

### Responsibility:

- initializes the application with the user's desktop settings;
- takes care of the event loop: performs event handling, it receives events from the underlying window system and dispatches them to the relevant widgets;
- knows about the application's windows;
- defines the application's look and feel.

- For non-GUI Qt applications, use QCoreApplication instead.
- The exec() method of the QApplication makes the application enter its event loop.
- When a Qt application is running, the event loop waits for user input, then events are generated and sent to the widgets of the application.
- The loop is terminated when any of the functions exit() or quit() is called.

Qt Designer

- Widgets are the basic building blocks for graphical user interface (GUI) applications built with Qt. E.g.: buttons, labels, textboxes, etc.
- A GUI component (widget) can be placed on the user interface window or can be displayed as independent window.
- A widget that is not embedded in a parent widget is called a window.
- Windows provide the screen space upon which the user interface is built.

# Qt GUI Components (widgets) II

Object-Oriented Programming

Ot GUI

Components (widgets)

- Windows visually separate applications from each other and usually provide a window decoration (show a title bar, allows the user to resize, position, etc).
- The Widgets module in Qt uses inheritance.
- All widgets inherit from QWidget, which is derived from QObject.

Qt Designer

- Widgets use the parenting system:
  - Any object that inherits from QObject can have a parent and children.
  - When an object is destroyed, all of its children are destroyed as well.
  - All QObjects have methods that allow searching the object's children.
  - Child widgets in a QWidget automatically appear inside the parent widget.

- QLabel is used for displaying text or an image.
- No user interaction functionality is provided.
- A QLabel is often used as a label for an interactive widget.
- For this use QLabel provides a useful mechanism for adding an mnemonic that will set the keyboard focus to the other widget (called the QLabel's "buddy").
- Is defined in the header <QLabel>.

```
QLabel label("Hello :)");
label.show();

### QLineEdit

- QLineEdit widget is a one-line text editor.
- A line edit allows the user to enter and edit a single line of plain text with a useful collection of editing functions, including undo and redo, cut and paste, and drag and drop.
- A related class is QTextEdit which allows multi-line, rich text editing.
- Is defined in the header <QLineEdit>.

```
QLineEdit lineEdit;
QLabel label("&Hello :)");
label.setBuddy(&lineEdit);

Layout management

Qt Designer

- The Qt layout system provides a way to automatically arrange child widgets within a widget to ensure that they
  make good use of the available space.
- Qt includes a set of layout management classes that are used to describe how widgets are laid out in an application's user interface.
- These layouts automatically position and resize widgets when the amount of space available for them changes, ensuring that they are consistently arranged and that the user interface as a whole remains usable.

 If a widget is added to or removed from a layout, the layout will automatically adapt to the new situation (the same thing happens when applying the show() or hide() functions for a widget).

 An absolute position can be specified for a widget using the function setGeometry(), which builds a rectangle using the given parameters (x and y positions, width and height).

### **Absolute positioning disadvantages**

- If the window is resized, the widgets with absolute positions remain unchanged.
- Some text may be truncated (large font or change in the labels).
- The positions and sizes must be calculated manually (errorprone, hard to maintain).
